

ZETHORA

Fair money for people and machines.

Lightpaper v0.2

Draft for public comment · October 2026

Wake Up From The Dream World.

Built by DeionRaven Labs · x.com/ZethoraNetwork

1. Summary

Zethora is a proposed Layer-1 blockchain that combines four properties no single network has brought together: Bitcoin's scarcity and mining, Solana's speed, Ethereum's programmability, and Monero-level privacy. It adds three things none of them build in: mining on ordinary home computers, coins that cannot be lost, and wallets for machines.

Zethora has no owner. It launches fairly: zero coins at genesis, no presale, no premine, no insider allocation. Every coin is mined, by anyone, from block one.

Status: design stage. The network does not exist yet. There is no Zethora token today. This document describes a proposed design and is published for public comment.

2. Why Zethora

Bitcoin began on home computers. Today it is mined in warehouses by machines built for a single purpose, and every balance and payment is public forever. Ethereum made money programmable but began with a presale. Solana is fast but asks for data-center hardware. Monero is private but slow and has no applications. Each excels at one or two things. None is fair, fast, private, programmable, and home-mineable at once.

Zethora's position is simple: **Bitcoin left your home. Zethora brings it back** — and makes it private, fast, and useful.

Property	Inspired by	In Zethora
Scarcity	Bitcoin	100,000,000 ZTHR, ever. Every coin mined.
Speed	Solana	~1 block per second. Everyday payments safe in ~10 seconds.
Programmability	Ethereum	Safe object-based smart contracts. Anyone can create tokens.
Privacy	Monero / Zcash	Private by default. Supply always provable.
Home mining	Early Bitcoin, Monero	CPU-friendly proof-of-work.
Can't-lose coins	New	Built-in recovery and inheritance.
Machine wallets	New	Devices hold funds under owner-set rules.

3. Principles

- **Fair launch.** Genesis holds 0 coins. No premine, presale, founder, or investor allocation.
- **No owner.** No admin key, pause switch, or freeze power exists for anyone, including the builders.
- **Fixed money rules.** Supply and issuance can never change. Software that changes them is not Zethora.
- **Privacy by default, honestly disclosed.** Anyone choosing transparency is clearly told what becomes public.
- **Security over speed of launch.** Audits, formal verification, and a long public testnet come first.
- **Home-computer rule.** If speed and decentralization conflict, a normal home computer must still be able to run a node.
- **No price promises.** Zethora makes no claims about the future price or value of ZTHR.

4. Monetary Policy

Parameter	Value
Ticker	ZTHR
Maximum supply	100,000,000 ZTHR
Divisibility	10 decimals · 1 zet = 0.0000000001 ZTHR
Supply at genesis	0
Issuance	Mining only. Each block pays a fixed fraction of the remaining supply (smooth decay, no halving cliffs)
First block reward	~0.2746 ZTHR (at 1 block per second)
Half mined	~8 years
90% mined	~27 years
After rewards fade	Miners paid by fees and a protocol fee pool
Tail emission / treasury	None / None

Formula. reward = floor(remaining supply / D), with D = 364,223,944 at one block per second. Integer math only; every node checks every block. The result: half the remaining supply is released every eight years. Bitcoin released half of its supply in its first four years and ~90% in about eleven; Zethora's slower curve gives people everywhere a fairer chance to take part.

Time	Total mined	Share of cap
Year 1	~8.3M	8.3%
Year 8	50M	50%
Year 16	75M	75%
Year 27	~90.4M	~90%
Year 50	~98.7M	~98.7%

5. Design Overview

5.1 Mining and consensus

Proof-of-work using RandomZ, a tuned variant of RandomX, the CPU-friendly algorithm proven by Monero since 2019. Blocks are arranged in a BlockDAG (GHOSTDAG-family ordering, as proven by Kaspa) so parallel blocks are kept rather than discarded, enabling ~1 block per second. A decentralized pool ships with the node so small miners get steady payouts with no pool operator holding funds. The mining algorithm receives a small scheduled tweak about every two years so specialized chips are never worth building.

5.2 Privacy

Sender, receiver, and amount are hidden by default using zero-knowledge proofs with no trusted setup. Transaction origins are hidden at the network level (Dandelion++, Tor/I2P). Owners may create view keys to share their own history voluntarily; no master key exists. An optional transparent mode lets exchanges and businesses operate openly; it exposes only the activity of whoever chooses it.

Privacy can never hide inflation. History shows the risk: Bytecoin and Zcoin were exploited by counterfeiting bugs in 2017, and in 2026 a four-year-old Zcash bug that could have minted unlimited coins was disclosed. Zethora requires turnstile accounting from day one — the private pool can never release more value than entered it — plus continuous supply proofs, multiple audits, formal verification, a bug bounty, and a staged rollout.

5.3 Programmability

Smart contracts use an object model in the Move language family (as in Sui and Aptos): every asset is an object with an owner, and the language itself prevents copying or silently destroying assets. Transactions that touch different objects run in parallel. Apps are immutable by default; an app may be upgradeable only if it declares so at launch, and wallets display that warning. No app can ever create ZTHR. Ethereum compatibility is planned for later.

5.4 Tokens

Anyone can create a token. By protocol rule, supply is fixed and tokens cannot be frozen or upgraded unless those powers are declared at creation and shown to users. DeionRaven Labs plans a launchpad with fair bonding-curve pricing, automatically locked liquidity, and a risk card on every token showing creator holdings, holder concentration, and powers — safer from hidden tricks, while honestly disclosing that market risk remains.

5.5 Fees

Fees are paid in ZTHR and target fractions of a cent, kept low through capacity rather than subsidy. An automatic base fee rises only when the network is full; optional tips go entirely to the miner. The base fee is split **60% to a fee pool** that pays miners over about 30 days, sustaining security for decades, and **40% burned** permanently, so holders' share of supply grows as usage grows. Nothing is printed to reward holders.

5.6 Wallets

Users hold their own keys, stored by default in the phone's secure chip; hardware wallets are supported. Recovery offers several independent paths — a backup phrase, an optional passkey synced through Apple or Google, the user's own spare devices, or optional trusted people (two of three) — with waiting periods and alerts so no one can quietly take control. Optional inheritance passes coins to chosen beneficiaries, including by claim code, after a period of inactivity with warnings first. Device wallets let cars, robots, and AI agents spend within limits their owner sets.

5.7 Nodes

A full node runs on a normal home computer. Old data is pruned with cryptographic proofs, phones run light nodes that verify rather than trust, and no central server exists for peer discovery. The reference software is open source and written in Rust. Sharding is researched in the background for the future.

6. Governance and Upgrades

Zethora is community-built. Changes are proposed as public Zethora Improvement Proposals (ZIPs), reviewed, and tested on testnet. Upgrades activate through a hybrid process: miners may activate early by signaling, but cannot block an upgrade forever, because it activates on a published date for nodes that choose the new software. The money rules can never be changed by any process. Community polls inform priorities but never decide security rules.

7. Security and Launch

Mainnet launches only after every gate passes:

- At least two independent audits, plus a dedicated audit of the privacy cryptography
- Formal verification of privacy circuits and supply rules
- Turnstile and supply checks verified on testnet
- Public bug bounty live
- Testnet attack drills: 51%, spam, counterfeiting, network isolation
- The three hardest integration problems solved and tested
- A normal laptop runs a full node at full network load
- A public testnet of at least six months

The launch date is announced one month in advance and the software is published beforehand. Full rewards begin at block one, with fast difficulty adjustment. The genesis block contains the hash of the latest Bitcoin block at launch time — proof that no one mined early — and the message:

"Wake Up From The Dream World"

8. Ecosystem

DeionRaven Labs is the lead builder of Zethora, not its owner. It holds no coins except those it mines or buys like anyone else, and earns through products built on top, competing on equal terms:

- The Zethora app: wallet, home-mining dashboard, phone remote
- A launchpad with protocol-backed safety guarantees and risk cards
- An AI compute marketplace where idle computers earn by running AI jobs and phone users earn for small tasks (planned, Phase 3)
- Family money tools: vaults, kids' funds, allowances, inheritance
- Later: AI products and devices that use Zethora natively

9. Roadmap

Phase	Focus
1. Specification	Core specs published for public comment (now)
2. Prototype	First working node
3. Public testnet	Minimum six months, open to all
4. Mainnet	Only when every launch gate passes
5. Ecosystem	Apps, launchpad, AI compute marketplace, devices

10. Get Involved

Read the specifications, open issues, and propose changes through ZIPs. Builders in Rust, cryptography, consensus, wallets, and security are welcome. Contributors receive credit — never coins. The fair launch stays fair.

Disclaimer. This document describes a proposed design that may change. It is not an offer to sell or a solicitation to buy any asset, not investment, legal, or tax advice, and makes no representation about the future price or value of any asset. The \$ZERO token on pump.fun is not part of Zethora and will not migrate. Any token claiming to be Zethora before mainnet is not Zethora.
